Sustainable Development Plan of Hartlepool: Analytical Essay

Introduction

The site is located in Hartlepool on the south western edge of the urban district of Hartlepool with a length of between 1.65 km and 2.65 km from the city. The site is located outside the most remote corners of Hartlepool's development and is currently in an open area. The vehicle's current access to the site is currently limited due to its use in rural areas. The gas base passes 200 mm below the ground through a stretch from north to south and the gas height gives 100 mm below the ground on the eastern road towards Macrae Road (Bruce, Wistow and Kramer, 2011). The header also crosses the underground site, one extending from corner to corner above the site near Al-Biek, and the other crossing the site's focal point from east to west near the current highway. Also, numerous overhead electrical cables cross the southern part of Peak (66 kV) and the southern part of the section closest to the A689 Staunton Road (11 kV). There is a culvert north-east of the site operated by Hartlepool City Hall. The reason for this report is to provide the foundations and conditions for learning the basics of organizing the renewable energy era in Hartlepool’s new sustainable plan. The possible stakeholders of the sustainable development plan

Stakeholders

The possible stakeholders of the sustainable development plan are engineers and the people who believe that renewable resources are vital in the town of Hartlepool. Engineers of the town are looking to work in the project because by working in this project they can attain their reputation in the international market because of the recognition that people of Hartlepool have given to them.

Executive Summary:

After the conference of nations united on climate change in Paris in December 2015 it was agreed that it would limit global warming temperatures o below 2 degree Celsius. The long term goal is to zero net emissions until the turn of the century nothing that progress has been made independently in 2018 and at regular intervals from today. Reflecting on the lower cost of low carbon increases with particular attention to reducing emissions there will be an opportunity to take risks. In 2020 all countries will seek to update their emission reduction agreements by 2030. The declaration on national energy policy states that the United Kingdom has significant resources in renewable energy, especially wind and tides. The costs of renewable energies are mainly in the development and support phase, since the activity itself is free which helps protect customers from the unpredictable but in general the cost of petroleum products. Various ideas have been proposed to make Hartlepool's infrastructure effective.

Discussion

Adjacent specialists are responsible for ensuring the development of a low-carbon renewable

energy period of 50 MW or less than the set limit. The Energy Minister considers the recommendations with a maximum allowable limit of over 50 megawatts under the 2008 Planning Act and the closest regulatory body is a legal adviser. However, the government is currently assigning the task of modifying this law so that all requests for internal wind energy development are taken into account by professionals in the regulation of the region (Smith, Pugh and McEvoy, 2012). The National Planning Policy Framework (NPPF) establishes departmental management strategies for sustainable development. One of the rules that the organization must support is “moving towards a low carbon future in a changing climate and expanding the opportunities to use renewable resources (for example, by developing renewable energy sources)

It did not include any studies on wind farm development and landscape capabilities nor an assessment of hartelpool’s landscapes the main developed areas. However there were three late apps for the massive wind turbines on Brenda road in southeast Hartelpool. These statements were made by the secretary of state but were revoked due to insufficient open debate. Brenda road together with the most substantial portion of the southeast of hartelpool is mostly modern and functional area of the city with the mechanical structures and charged variables. The area is closest to this region which is the central aspect of researching the potential of wind farms is in Bellingham and Hartlepool (Zone 27). This region is considered a moderate vulnerability and the study indicates that a 'small to medium' wind farm (up to 6 turbines) associated with the mechanical development of southeast Hartlepool could be suitable (Zhu, Romain and Williams, 2016). However the study also indicated that the potential in zone 27 might be limited by the number of restrictions in the region. The 2006 Hartlepool domestic plan adopted with the PU7 approach guides the idea of renewable energy. The procedure provides general assistance to renewable energy companies including achieving more comprehensive environmental and financial benefits.

Also the agreement states that a record of effects on the appearance and personality and comfort of residents the environment and radar and media communications should be maintained. As for the recommendations for wind turbines the approach expresses that the geology and design of the turbines will be taken into account and all reasonable measures will be taken to reduce the impact (Banos et al 2011). Exposed energy loss/heating plans may be exposed to a critical commitment to energy from renewable sources. However the heat source must have a minimum number of potential customers to make such plans appropriate. Previous research has shown that there may be plans to heat the Hartlepool area in connection with the events linking the city and the marina. However, plans are likely to require funding for prizes and sponsorships to allow them to be admitted (Ellabban, Abu-Rub and Blaabjerg, 2014)
